# ACIDS, ALKALIS, AND THE pH SCALE

The pH scale is a way of gauging the acidity or alkalinity of a solution. It is calculated using:  $\text{pH} = -\log_{10}[\text{H}^+]$ . Adding an acid to water increases the  $\text{H}^+$  ( $\text{H}_3\text{O}^+$ ) concentration, and decreases the  $\text{OH}^-$  concentration. An alkali does the opposite.

	pH	$\text{H}^+$ CONCENTRATION (in moles per litre)	$\text{OH}^-$ CONCENTRATION (in moles per litre)	EVERYDAY EXAMPLE
<b>ALKALINE</b> Turquoise → Blue → Purple	14	$1 \times 10^{-14}$	1	Drain Cleaner 
	13	$1 \times 10^{-13}$	0.1	Bleach 
	12	$1 \times 10^{-12}$	0.01	Ammonia 
	11	$1 \times 10^{-11}$	0.001	Soap 
	10	$1 \times 10^{-10}$	$1 \times 10^{-4}$	Antacid Tablets 
	9	$1 \times 10^{-9}$	$1 \times 10^{-5}$	Baking Soda 
	8	$1 \times 10^{-8}$	$1 \times 10^{-6}$	Seawater 
<b>NEUTRAL</b> Green	7	$1 \times 10^{-7}$	$1 \times 10^{-7}$	Pure Water 
<b>ACIDIC</b> Red → Orange → Yellow	6	$1 \times 10^{-6}$	$1 \times 10^{-8}$	Urine (average) 
	5	$1 \times 10^{-5}$	$1 \times 10^{-9}$	Black Coffee 
	4	$1 \times 10^{-4}$	$1 \times 10^{-10}$	Tomato Juice 
	3	0.001	$1 \times 10^{-11}$	Soda 
	2	0.01	$1 \times 10^{-12}$	Lemon Juice 
	1	0.1	$1 \times 10^{-13}$	Stomach Acid 
	0	1	$1 \times 10^{-14}$	Battery Acid 

# PTC Testing

PTC stands for phenylthiocarbamide. Also known as phenylthiourea, the chemical structure of PTC resembles toxic alkaloids found in some poisonous plants.

Taste buds are filled with **gustatory cells** - the cells that do the tasting. The tip of each gustatory cell protrudes through a pore on the surface of the tongue.

**Nerves** carry signals from the gustatory cells to the brain.

The tip of each gustatory cell is covered with an assortment of **bitter taste receptors**, which can detect a wide variety of compounds. Stimulation of any of these receptors sends a signal to the brain: bitter!

# Microscopy

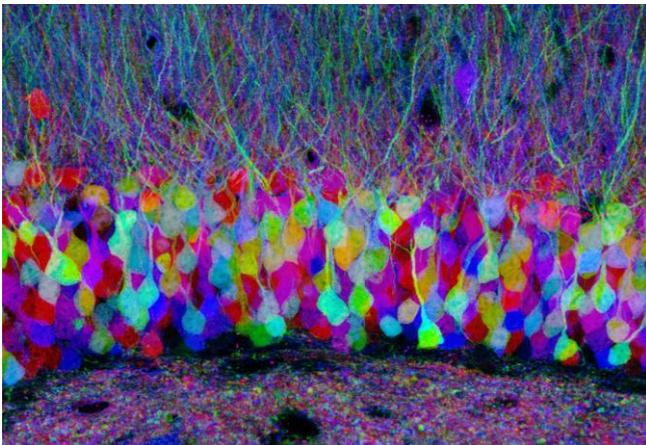

**Table 1-1** Different Types of Light Microscopy: A Comparison

Type of Microscopy	Light Micrographs of Human Cheek Epithelial Cells		Type of Microscopy
<p><b>Brightfield (unstained specimen):</b> Passes light directly through specimen; unless cell is naturally pigmented or artificially stained, image has little contrast.</p>			<p><b>Phase contrast:</b> Enhances contrast in unstained cells by amplifying variations in refractive index within specimen; especially useful for examining living, unpigmented cells.</p>
<p><b>Brightfield (stained specimen):</b> Staining with various dyes enhances contrast, but most staining procedures require that cells be fixed (preserved).</p>			<p><b>Differential interference contrast:</b> Also uses optical modifications to exaggerate differences in refractive index.</p>
<p><b>Fluorescence:</b> Shows the locations of specific molecules in the cell. Fluorescent substances absorb ultraviolet radiation and emit visible light. The fluorescing molecules may occur naturally in the specimen but more often are made by tagging the molecules of interest with fluorescent dyes or antibodies.</p>			<p><b>Confocal:</b> Uses lasers and special optics to focus illuminating beam on a single plane within the specimen. Only those regions within a narrow depth of focus are imaged. Regions above and below the selected plane of view appear black rather than blurry.</p>
